S-parameter characterisation of LMS7002M Field Programmable RF MIMO Transceiver Integrated Circuit

Chip version:	LMS7002M
Chip revision:	01
Document version:	01
Document revision:	05
Last modified:	24/08/2015 13:40:00

Table of Contents

1. Introduction.....	8
1.1 Principles of S-parameter Measurements.....	8
2. Design of the Lime Characterization Boards	10
2.1 S-parameter Files.....	10
3. Example Simulation	15
3.1 Simulation of the LMS7002M Evaluation Board LNAWA input.....	15
3.2 Common difficulties with simulating with S-parameters	16
3.3 S-parameters and TX Output.....	17
4. Measured S-parameter Graphs	18
4.1 LNAH channel A sample 1	19
4.2 LNAH channel A sample 2	24
4.3 LNAH Channel A Sample 3.....	29
4.4 LNAH Channel B Sample 2	34
4.5 LNAH Channel B Sample 3	39
4.6 LNAL Channel A Sample 1	44
4.7 LNAL Channel A Sample 2	51
4.8 LNAL Channel A Sample 3	58
4.9 LNAL Channel B Sample 1	64
4.10 LNAL Channel B Sample 2	71
4.11 LNAL Channel B Sample 3	78
4.12 LNAW Channel A Sample 1.....	85
4.13 LNAW Channel A Sample 2.....	91
4.14 LNAW Channel A Sample 3.....	98
4.15 LNAW Channel B Sample 1	105
4.16 LNAW Channel B Sample 2	112
4.17 LNAW Channel B Sample 3	119

Revision History

Version 01r00

Started: 24th April, 2015

Finished: 15th May 2015

Initial version.

Version 1.1

Started 15th June 2015

Finished 17th June 2015

Added graphs of s-parameter files.

1 Introduction

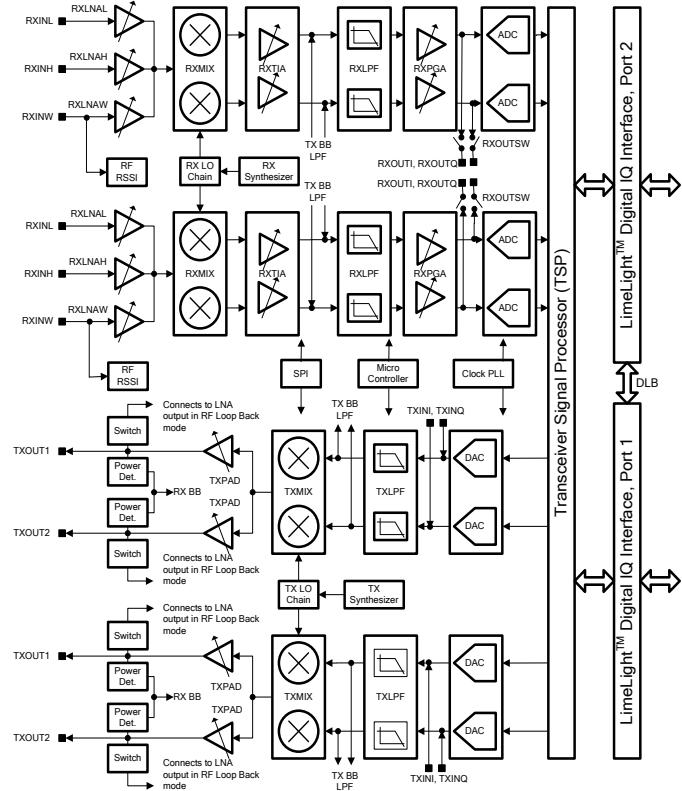

Figure 1 LMS7002M Architecture

The LMS7002M is a field programmable software defined radio transceiver integrated circuit radio system covering the frequency range from 100kHz to 3800MHz. A block diagram of the transceiver is shown in *Figure 1*. The transceiver consists of two MIMO channels each with 3 LNA inputs and 2 TX outputs, ADC/DAC, synthesizers and signal processing.

This report focuses on the characterisation of the six LNA inputs.

1.1 Principles of S-parameter Measurements

Scattering parameters (s-parameters) are used to characterize various microwave devices in the frequency domain. Measurements of transmission and reflection are made on the device under test. S-parameters are usually measured with a Vector Network Analyzer (VNA) which measures both magnitude and phase. (Scalar Network Analyzers only measure magnitude). Most VNAs measure only 2-ports. All VNAs require calibration before accurate measurements can be made. The most commonly used calibration kits are Short, Open, Load, Through (SOLT) and the Line, Reflect, Match (LRM). The calibration kit calibrates to “the reference plane” of the measurements. For a SOLT calibration, the reference plane is the external interface surface of the connectors.

Generally s-parameter measurements are made on a test board or fixture and the measurements have to be post processed to remove the effects of the test fixture connections on the measurements. This process is commonly called de-embedding.

De-embedding is generally carried out in a circuit simulator environment. The components to be removed are entered as negative line lengths or negative component values. The components being de-embedded closest to the reference plane are de-embedded first from the measured s-parameter file. The components being de-embedded closest to the device being characterized are closest to the simulation port.

Measured s-parameters can be affected by the amplitude of the sweep from the VNA. Too low and the measurements will be noisy. Too high, and semiconductor devices will deviate from their small signal behavior. Typically -20dBm or -30dBm VNA output power is advisable for s-parameter measurements of the LMS7002.

2 Design of the Lime Characterization Boards

Lime has used the following principles to minimize errors in the de-embedding process:

- (i) Use of Rogers 4350 for the microstrip environment and FR4 for noncritical layers.
- (ii) Track thickness of the test fixture are kept reasonably wide to give a well-defined electrical length and characteristic impedance. Bends are only 45 degrees to remove the need of chamfered bends.
- (iii) Physical lengths of lines kept short as possible.
- (iv) Only very short lengths of lines of minimum thickness and space are used.
- (v) The number of passive devices included in the test fixture RF path are kept to a minimum with values which have the least effect over the frequency range of the measurements.
- (vi) Calibration structures to model SMA connectors.

The some of the characterization boards used are shown in *Figure 2*.

Figure 2 S-parameter Characterisation Boards.

2.1 S-parameter Files

S-parameters were measured with an Agilent (Keysight) E5071C using an 8509X e-cal module and then de-embedded. The de-embedded s-parameter files are in LMS7002M_LNA_sparams.zip. The zip file contains measurements for 2-3 samples of each of the 6 LNAs. They are stored in the directories shown in **Table 1**. Where A and B denote MIMO channels A and B. H, L and W denote high band, low band, and wideband LNAs. The files in each directory are listed in **Table 2**, **Table 3** and **Table 4**.

Files were measured for different gains and different programmable input capacitor settings (Cap_Var). LNAW and LNAL also have a programmable input short circuit switch and this is also measured. The LNA gain is always relative to maximum gain. Absolute gain is frequency dependent.

Each s-parameter file is a 2-port file with each port corresponding to one of the two inputs of the differential LNA. The reference plane of the de-embedded s-parameters is the package pin. PCB pads have been de-embedded.

3 Example Simulation

In this chapter the LMS7002M evaluation board S-parameters are measured and compared with simulated results.

3.1 Simulation of the LMS7002M Evaluation Board LNAWA input.

A schematic was generated of the LNAWA part of the LMS7002M evaluation board using the default RF matching component values. The s-parameters of the LNAWA characterization was used to represent the impedance of the LNA. Manufacturer's S-parameter files were used to describe the transformer balun, capacitors and inductor in the matching network.

A comparison of the measured and simulated results are shown in *Figure 3* for max LNA gain and minimum programmable input capacitance (set to 0). It can be seen that the s-parameter simulations were accurate to about 2.5GHz, but above this frequency the simulation becomes progressively more sensitive to sample to sample variation of both passive and active components.

The effect of LNA gain on match is shown in *Figure 4*, and it can be seen clearly that the LNA gain has almost no effect on matching.

The effect of the LNA programmable input capacitor is shown in *Figure 5*. This programmable input capacitor provides a convenient method to adjust a matching network for component tolerances without the need to change physical components.

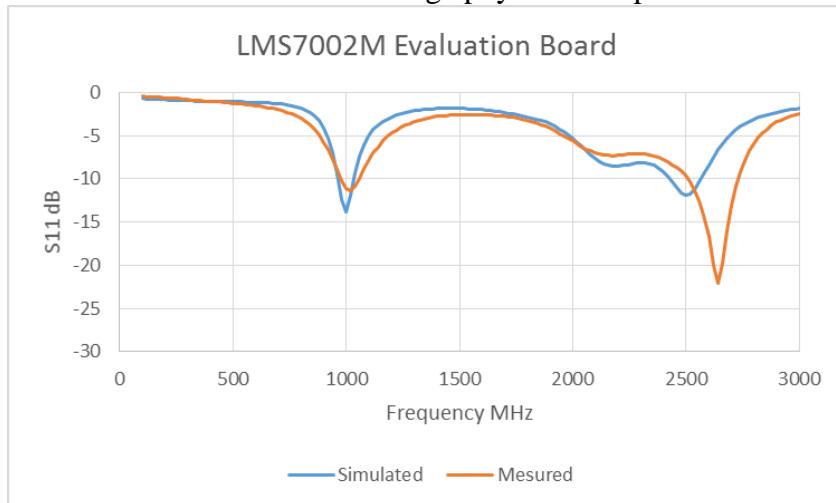

Figure 3 Simulated and Measured S_{11} of LMS7002M LNALA.

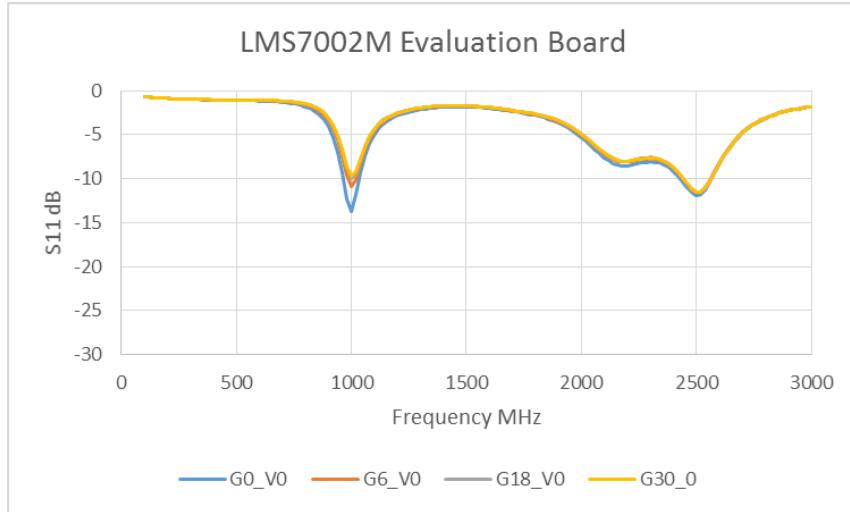

Figure 4 Simulated variation of S_{11} of LMS7002M LNALA with LNA gain.

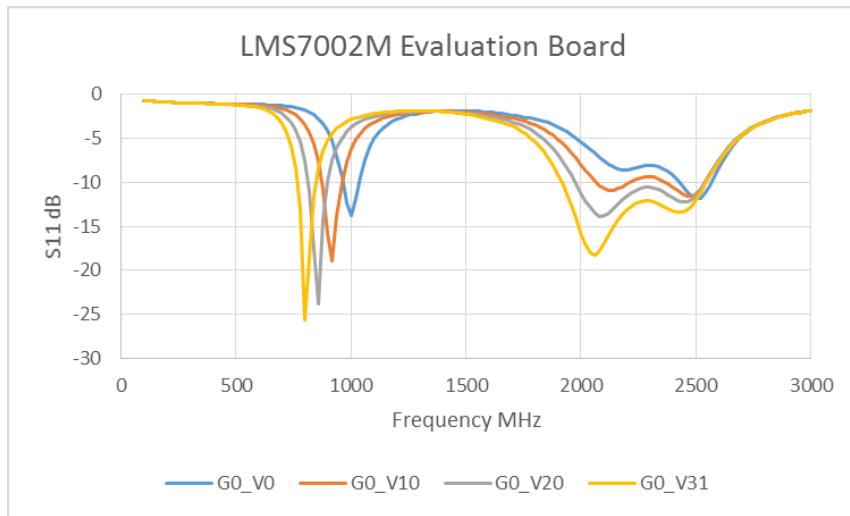

Figure 5 Simulated variation of S_{11} of LMS7002M LNALA with input capacitance code.

3.2 Common difficulties with simulating with S-parameters

When simulating with s-parameters, a number of difficulties can affect the agreement between measured and simulated s-parameters.

Not all manufacturers provide s-parameter data or equivalent circuit models for their components. Sometimes s-parameters are provided, but the frequency range may be unsuitable, or the reference plane poorly defined or the measurements not fully de-embedded.

Many ordinary devices, such as capacitors and inductors, have losses which are frequency and dielectric dependent, which cannot be easily modelled as a simple lumped element equivalent. Such components are essential for bias and DC blocking of active devices.

Passive devices such as surface mount capacitors are made by a variety of manufacturers to the same value, but may have significant differences in parasitics.

Some devices may have significant sample to sample variation, such as wound transformers and small value capacitors.

Many common PCB tools draw tracks as lines of different thicknesses with rounded ends and these do not readily convert into common microwave library parts.

PCB substrate materials are compressed together to make a multilayer boards, the resultant thicknesses of individual layers will have some tolerance. FR4 has a dielectric constant that often varies with distance due to the grouping of glass fibers in the weave, it is also sensitive to atmospheric moisture. Etching of small tracks needed for modern miniature devices also leads to uncertainty of track thicknesses and spaces. Most PCBs are covered with a layer of solder resist (often of unspecified thickness with unspecified dielectric properties) and this significantly affects coupling of closely spaced tracks.

3.3 S-parameters and TX Output

S-parameters for the TX outputs have not been provided. This is because the TX outputs are essentially current sources and best performance is obtained through a “load pull” approach rather than conjugate matching. Load pull is the method of choice for power amplifier optimization. For low frequencies <2.5GHz, no matching is generally needed for the LMS7002M TX outputs when loaded with 50R and RF components are placed close to the device.

The Maury 1819B triple stub tuner is very useful for “quick” load pull measurements over 800-4000MHz. Normally for best OIP3 performance at maximum output power the tuner has to be tuned a dB or so away from maximum output power.

4 Measured S-parameter Graphs

We show graphs of the de-embedded measurements for several samples of each LNA for different operating conditions in *Figure 6* to *Figure 217*. S11 and S22 correspond to the two differential inputs of each LNA.
